

Compared with building a new base station, digital repeater is a more economical solution to improve signal coverage and communication quality. And it is easy to install and maintain, which can help operators quickly achieve coverage results.

The digital repeater is an amplifier between the base station and the mobile terminal. It receives the strongest signal from the base station through the donor antenna, linearly amplifies the signal and transmits it to the weak signal/blind area through the indoor signal distribution system. At the same time, the mobile signal can also pass Amplify and transmit to the base station via the opposite direction.
